RE: FORENSIC GEOTECHNICAL INVESTIGATION
FORMER LABCORP BUILDING
MERIDIAN, MISSISSIPPI

Dear Mr. Luke:

Pritchard Engineering, Inc. appreciates the opportunity to participate as geotechnical consultant for the project captioned above. At your request, Pritchard Engineering, Inc. performed two (2) soil borings and subsequent laboratory analysis in an effort to determine the subsurface conditions present along the front of the structure referenced above. Presented herewith are the following:

- A summary of the field exploration and laboratory methods employed
- Logs of two (2) borings including results of laboratory analysis'.
- Commentary and recommendations regarding the probable cause(s) of structure demise and potential mitigation options.

PROMPT / SITE CHARACTERISTICS

This investigation is prompted by signatures of foundation and structure distress along the front entry and authorized verbally by Mr. Bob Luke, architect and consultant.

The subject structure is a former grocery re-purposed by LabCorp which is currently abandoned. It is located at the intersection of Donald Avenue and E Street in Meridian, Mississippi; just northwest of the prior Village Fair Mall. Handheld GPS coordinates obtained by the driller in proximity of boring (1) are N 32° 21' 21.1" and W 88° 41' 51.0". Ground cover beyond the footprint of the structure consists primarily of paved parking areas and access drives. The surrounding topography is relatively flat and surface drainage appears poor.

FIELD INVESTIGATION

Two (2) borings were performed at locations and to depths selected by Pritchard Engineering. Appendix (C) provides a schematic depicting the approximate boring locations.

Drilling was accomplished by the dry auger method utilizing continuous flight auger advanced by a tractor mounted Giddings Model TS-35 hydraulic boring rig and were terminated at a depth of fifteen (15) feet below the existing site elevation. Shelby tubes were advanced (See ASTM D-1587) at selected depths to provide "undisturbed" specimens for visual classification and determination of shear strength and compressibility parameters by testing in unconfined compression and one-dimensional consolidation. Standard penetration tests (See ASTM D-1586) were also conducted at locations and intervals specified by the geotechnical engineer. The standard penetration resistance (N) value is the number of blows required to drive a standard 18-inch split-barrel sampler the final 12 inches utilizing a 140-pound hammer and a freefall height of 30 inches. Standard penetration values provide an indication of soil consistency and can be utilized in formulating design recommendations through empirical relations including but not limited to bearing capacity and potential settlement under loading conditions. "N" values are depicted by depth and location on the boring logs.

Representative specimens of the various soils encountered were retrieved at changes in strata and at intervals not exceeding 2 feet in depth. Samples retrieved during the field investigation were immediately placed in sealed containers to preserve their physical characteristics for transportation and future analysis in the laboratory.

The depth at which free water was first detected during drilling is indicated on the boring logs. Prior to closure, the depth to ground water and/or borehole caving was determined. This information is also recorded on the boring logs and was obtained after an elapsed period of approximately 1 to 2 hours.

LABORATORY ANALYSIS

Procedures employed in performing laboratory analysis were accomplished in general accordance with applicable American Society for Testing and Materials (ASTM) standard specifications for quality assurance. Tests were conducted on representative samples of the various soils encountered as designated by the Engineer. A list of the tests performed including a summary of the results obtained is presented as follows:

(Soil Classification) – ASTM D-2487

All soil samples were classified both visually and in accordance with criteria stipulated by the Unified Soil Classification System. (See boring logs.) Under the Unified Soil Classification System, coarse-grained soils (gravels and sands) are classified based upon grain-size. Fine-grained materials (silts and clays) are classified on the basis of plasticity (PI) as related to the Casagrande "A" line. For your convenience, a description of the symbols employed by the Unified Soil Classification and their meaning is presented as Appendix (A). Where appropriate, dual symbols are employed to signify borderline soils.

(Water Content) – ASTM D-2216

In-situ (or field) moisture contents were determined by placing extracted samples in sealed containers immediately upon removal from the drill cavity. Highly saturated soils were encountered near the surface in Boring (1). Otherwise, information generated from the analysis performed indicates in-situ moisture

contents were within the anticipated range for the soil types encountered and climatic season. Moisture content data is presented on the boring logs as W (%).

(Liquid and Plastic Limits) – ASTM 4318

Liquid and plastic limits, commonly referred to as Atterberg Limits, were performed on representative samples of the cohesive soils encountered. The plastic limit (PL) is the moisture content representing the lower boundary range of plastic behavior of a soil. The liquid limit (LL) is the moisture content representing the upper range of plastic behavior; above which a soil will essentially have the shear strength of a fluid. Both values are expressed as percent (%) moisture. The plasticity index (PI) is the numerical difference between the liquid limit and plastic limit and is utilized in soil classification and empirical relations developed regarding volume change, strength, and permeability. Data generated from this investigation indicates the plasticity index (PI) of the clays identified within the upper soil horizon ranges from 9 to 23. Based on this information these soils are considered to have a low shrink-swell potential which should not be adversely impacting the building.

(Shear Strength)

Shear strength tests were performed on undisturbed and remolded specimens of the various soils encountered. Methods employed in assessing shear strength were designated by the geotechnical engineer and are briefly summarized as follows:

- **(Pocket Penetrometer)**

  Selected cohesive soil specimens were tested utilizing a pocket penetrometer. This procedure allows for a quick approximation of the unconfined compressive strength of a soil through correlation of penetration of a calibrated plunger. Results are indicated as tons per square foot (tsf) by sample depth on the boring logs and represent the average of a minimum of four (4) readings per specimen.

- **(Unconfined Compression Test) – ASTM 2166**

  The unconfined compression test provides a relatively quick and economical approximation of the unconsolidated and undrained shear strength of a cohesive soil. Testing involves subjecting an "undisturbed" cylindrical sample of the soil (usually extracted from a Shelby tube) to a uniformly increasing load under controlled stress or controlled strain conditions until failure is reached through shear or excessive strain. The cohesive shear strength (c) is equivalent to one-half of the maximum normal stress realized during the test effort. Test results indicate strengths range from approximately 0.8 to 4.6 kips per square foot (ksf) and are presented as unconfined compressive strength on the boring logs and as Appendix (B).

SOIL PROFILE

The generalized soil profile presented is based upon engineering interpretation of the boring logs and related laboratory analysis as presented in Appendix (B).

Nominal thickness of the asphalt pavement at the drilling locations was 8". We would note that an additional layer of asphalt underlain by a granular subbase was encountered at a depth of approximately 3 feet in boring (1) which may suggest a former parking area was overlain by new construction. Beneath these materials interbedded low to medium plasticity sandy and/or silty clays

conforming to Unified Classification CL were identified. Consistency of these soils as estimated by the driller and verified by standard penetration resistance "N" values of zero (0) to 8 ranges from **very soft** to medium stiff and would generally be considered as **very soft** to **soft**.

The soils described are superimposed on loose fine silty clayey sand (Unified Classification SM-SC) initially intercepted at a depth of approximately 13 feet in boring (1) which extended to the limits of exploration.

Highly saturated soils were noted at shallow depth in boring (1) with free water encountered at a depth of approximately 12 feet in boring (2). Caving of the drill cavity at 3.5' prohibited a subsequent groundwater observation at boring (1). Depth to groundwater as observed and recorded approximately 2 hours after removal of the drill tool say 9 feet in boring (2). The reader is advised the field investigation was accomplished within a period of above average precipitation. Migration of groundwater is common within the lean clays and permeable sands and the phreatic surface is anticipated to fluctuate with the climatic season. Also, localized abnormalities in groundwater levels may result from random fill or subterranean utility installations.

COMMENTARY / RECOMMENDATIONS

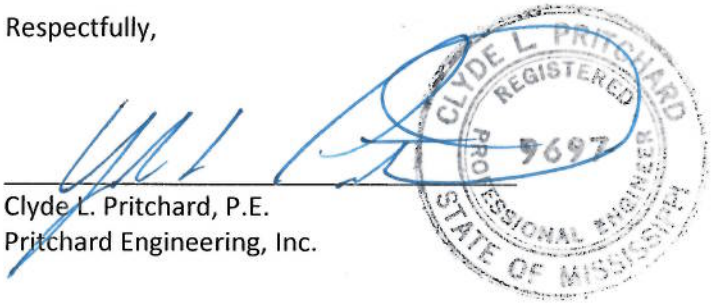
Based upon the information generated the probable causes of structure demise and distress realized to date include;

- A foundation system which is inadequate for the very low bearing capacity of the underlying soils, and
- Immediate distortion and subsequent consolidation of the very soft to soft clays upon loading.

At this juncture we advise installation of a minimum of two (2) shallow test pits to reveal the structure foundation(s); the geometry and composition of which to be evaluated by the geotechnical engineer. if the foundation is of sufficient integrity the system may be retro-fitted with A.B. Chance type helical piers. For estimating purposes, we would project single or double helical units bearing a minimum of twenty (20) feet beneath the existing site elevation(s) within the lower sand stratum. We advise pier installations be accomplished by a certified installer exhibiting a minimum of five (5) years of experience. Pier spacings and allowable capacities should be developed or verified based upon results of a test installation monitored by the geotechnical engineer.

Feel free to contact us should you have any questions regarding the information provided or if we may be of additional service.

Respectfully,



Clyde L. Pritchard, P.E.

RE: SUPPLEMENTAL BORINGS
FORMER LABCORP BUILDING
MERIDIAN, MISSISSIPPI

Dear Mr. Armstrong:

Submitted herewith are boring logs depicting the results of subsurface exploration and laboratory analysis performed on samples collected from each of two (2) supplemental borings conducted at the site captioned above. Said investigation intended to provide geotechnical parameters for canopy foundation design as outlined in our proposal of April 15, 2021. A site schematic illustrating the boring locations accompanies this document. Commentary and recommendations resulting from this effort are presented as follows.

SOIL PROFILE

Prevalent near surface soils identified at the locations investigated consist of low to medium plasticity sandy and/or silty clays. According to the criteria stipulated by the Unified Soil Classification System these soils are designated CL (lean clay) or CL-SC (borderline sand-clay). The extent to which the upper soil horizon represents relatively undisturbed geologic deposition or materials relocated or imported in prior site development is unknown. Consistency of the surficial clays as estimated by the driller and verified by standard penetration resistance "N" values of 4 to 7 ranges from **soft** to medium stiff.

Poorly graded fine silty and/or clayey sands and medium coarse sands were intercepted at depths of approximately 6.5 to 7 feet which extended to the limits of exploration. Appropriate Unified classifications for the sands are SM, SM-SC, SP, and SM-SP. Consistency of the lower sand strata as estimated by the driller and verified by standard penetration resistance "N" values of 5 to 14 ranges from **loose** to medium dense.

Free water was detected as the borings were advanced at depths of approximately 6.5 to 7 feet at the lower sand contact. Each of the boreholes caved at 6 to 8 feet with groundwater observed at 6 to 7 feet. The reader is advised the field investigation was accomplished within a period of above average rainfall and the phreatic surface observed is subject to change with climatic conditions.

FOUNDATION RECOMMENDATIONS

It is our understanding the project involves a "lean to" type annex to the parent structure for covered vehicle parking. Minimal grading is anticipated in site development. This investigation has revealed **soft** and **loose** materials within the zone of influence which pose a potential for excessive total and/or differential settlement. With respect to same we advise the following recommendations for utilization of reinforced concrete spread footings.

- Over-excavate area beneath and extending 1.5 feet beyond perimeter of future spread foundations to a depth of 4 feet beneath existing site elevation.
- Install 8 oz. non-woven geotextile on exposed subgrade in accordance with manufacturers recommendations.
- Backfill with initial 12" lift of Size No. 610 crushed limestone with minimal compactive effort. **DO NOT VIBRATE**.
- Backfill to design subgrade elevation in maximum loose lifts of 8"; each compacted to 95% of maximum dry density. **DO NOT VIBRATE**.
- Design shallow spread foundation for a maximum allowable soil pressure of 2400 psf.

All foundation members should be adequately reinforced to resist differential movement and as stipulated by applicable American Concrete Institute (ACI) specifications.

The allowable pressure quoted herein is intended to provide a factor of safety of 2.6 to 3.6 with respect to ultimate or bearing capacity failure of the supporting soils with a maximum anticipated settlement of 0.5 inches which is contingent upon proper placement and compaction of backfill during the grading process. Maximum anticipated differential settlement between adjacent columns is 0.25".

Feel free to contact us should you have any questions regarding the information provided or if we may be of additional service.

Respectfully,

Clyde L. Pritchard, P.E.
